Linked list segments

```c
struct list_node {
    int data;
    struct list_node* next;
};
typedef struct list_node list;

bool is_segment(list* start, list* end) {
    if (start == NULL) return false;
    if (start == end) return true;
    return is_segment(start->next, end);
}

struct linkedlist_header {
    list* start;
    list* end;
};
typedef struct linkedlist_header linkedlist;

bool is_linkedlist(linkedlist* L) {
    if (L == NULL) return false;
    return is_segment(L->start, L->end);
}
```

In lecture, we talked about the `is_segment(start, end)` function that tells us we can start at `start`, follow `next` pointers, and get to `end` without ever encountering a `NULL`. (We won’t worry about the problems with getting `is_segment` to terminate in this recitation.) A linkedlist is a non-NULL pointer that captures a reference to both the start and end of a linked list.

Here’s an example of a specification function that uses `is_segment` as a precondition.

```c
bool eq(list* start1, list* end1, list* start2, list* end2) {
    //@ requires is_segment(start1, end1);
    //@ requires is_segment(start2, end2);
    {
        if (start1 == end1 && start2 == end2) return true;
        if (start1 == end1 || start2 == end2) return false;
        return start1->data == start2->data
            && eq(start1->next, end1, start2->next, end2);
    }
}
```

**Checkpoint 0**

Why are the pointer dereferences on lines 7 and 8 safe?
Creating a new linked list

Here’s the code that creates a new linked list with one non-dummy node. Suppose `linkedlist_new(12)` is called.

```c
linkedlist* linkedlist_new(int data)
//@ensures is_linkedlist(result);
{
    list* p = alloc(list);
    p->data = data;
    p->next = alloc(list);
    linkedlist* L = alloc(linkedlist);
    L->start = p;
    L->end = p->next;
    return L;
}
```

Checkpoint 1

For each of lines 4–9 (inclusive) draw a diagram that shows the state of the linked list after that line executes. Use X for struct fields if we don’t care about their values.
Adding to the end of a linked list

We can add to either the start or the end of a linked list. The following code adds a new list node to the end, the way a queue would:

```c
void add_end(linkedlist* L, int x) {
//@requires is_linkedlist(L);
//@ensures is_linkedlist(L);
{
    list* p = alloc(list);
    L->end->data = x;
    L->end->next = p;
    L->end = p;
}
```

Checkpoint 2

Suppose `add_end(L, 3)` is called on a linked list `L` that contains before the call, from start to end, the sequence (1, 2). Draw the state of the linked list after each of lines 5–8 (inclusive). Include the list struct separately before it has been added to the linked list.

6.

7.

8.
Using *is_segment* as a loop invariant

A loop invariant must be initially true, must be preserved by every iteration of the loop, and together with the negation of the loop guard must imply the postcondition.

**Checkpoint 3**

What are the loop invariants we need to prove the correctness of this function?

```c
linkedlist* copy(linkedlist* L)
//@ requires is_linkedlist(L);
//@ ensures is_linkedlist(result);
//@ ensures eq(L->start, L->end, result->start, result->end);
{
    linkedlist* N = alloc(linkedlist);
    N->start = alloc(list);
    list* o = L->start;
    list* n = N->start;
    while (o != L->end)
    {
        n->data = o->data;
        n->next = alloc(list);
        o = o->next;
        n = n->next;
    }
    N->end = n;
    return N;
}
```

**Termination**

Termination arguments about linked lists are often a bit more abstract than what we have experienced in the past.

**Checkpoint 4**

The loop terminates because

is strictly decreasing at each iteration of the loop and can never get smaller than __________
where the loop guard evaluates to __________.
